

Contact Management System

Abstract

The Contact Management System is a software application developed to store, organize, and manage contact information efficiently. The system enables users to perform essential operations such as adding, viewing, searching, updating, deleting, and sorting contact records. Each contact contains details such as Contact ID, Name, Phone Number, Email Address, and Address. The application is designed using Java and follows the principles of Object-Oriented Programming (OOP) to ensure modularity, reusability, and maintainability. It uses data structures such as ArrayList for storing contact information and implements search and sorting algorithms to improve data retrieval and organization. The system also validates user input and prevents duplicate contact entries based on Contact ID or Phone Number. This project provides a simple, user-friendly interface that helps users maintain personal or professional contact information securely and efficiently. It minimizes manual record-keeping, reduces data redundancy, and improves the accuracy and speed of contact management. The Contact Management System serves as an effective mini project for learning Java programming, file handling, data management, and basic software development concepts.
